LAB WORK 2: CLASS 3

Java Real-Time – Synchronization and Communication Mechanisms

2025 - 2026

- ☐ [Some organization structure for Labwork2](#)
- ☐ [Why Threads?](#)
- ☐ [Threads – some aspects to consider](#)
- ☐ [Identification of needed Java Threads for Lab2](#)
- ☐ [Short-lived Threads](#)
- ☐ [Long-lived Threads](#)
- ☐ [Synchronization with a Semaphore](#)
- ☐ [Blocking queue example](#)
- ☐ [CalibrationThread](#)

- ❑ Having the class **Storage.java** already developed (DLL), at the Java side we need to organize our classes into a more logical and straightforward way.
- ❑ This should be done by aggregating the storage functionality as several well identified classes, some of them as Java threads.
- ❑ For instance, we can define concrete classes for axis operation and a class named mechanism, which aggregates the functionality for the cell movements, the switches, and the LEDs.

THE AXIS INTERFACE

REVIEW

Let's start by providing an interface definition for the Axis: Java interface -> [Axis.java](#)

The screenshot shows the Visual Studio Code editor with a project named 'labwork2'. The Explorer sidebar on the left shows the file structure: .vscode, bin, lib, src, App.java, Axis.java, AxisX.java, Storage.h, Storage.java, and README.md. The Axis.java file is selected. The editor window shows the following code:

```
src > J Axis.java > ...
1
2 public interface Axis {
3     public void moveForward();
4     public void moveBackward();
5     public void stop();
6     public int getPos();
7
8     // new method to implement in JAVA
9     public void gotoPos(int pos);
10
11 }
12
```

An **interface** is a completely "**abstract class**" that is used to group related methods with empty bodies

https://www.w3schools.com/java/java_interface.asp

A class that implements a specific interface must implement the methods of the interface.

The interface has several methods that are used in each axis.

Although each axis has distinct implementation, in an abstract way they behave similarly.....

As such, interface **Axis** specifies and describes the behavior of each axis in an abstract way.

CLASS AXISX, AXISZ and AXISY

REVIEW

```
Welcome  J App.java  J Axis.java  J Storage.java  J AxisX.java •
src > J AxisX.java > ...
1  public class AxisX implements Axis{
2      @Override
3      public void moveForward() {
4          Storage.moveXRight();
5      }
6
7      @Override
8      public void moveBackward() {
9          Storage.moveXLeft();
10     }
11
12     @Override
13     public void stop() {
14         Storage.stopX();
15     }
16
17     @Override
18     public int getPos() {
19         return Storage.getXPos();
20     }
21
22     @Override
23     public void gotoPos(int pos) {
24         // TODO Auto-generated method stub
25         throw new UnsupportedOperationException(message:"Unimplemented method 'gotoPos'");
26
27         //to be developed in JAVA
28     }
29 }
30
```

The same for AxisZ.java and AxisY.java

Each concrete **axis** can follow the **Axis interface** and implement the concrete functionality of each Axis's methods.

When a class implements an axis, it must **implement all** the interface's methods.

Based on the given interface, try develop **three classes** for each **axis** existing in the physical system.

THE CLASS MECHANISM

REVIEW

Create a new class **Mechanism.java**

```
src > J Mechanism.java > Mechanism
1
2 public class Mechanism {
3
4     public void ledOn(int ledNumber){
5         Storage.ledOn(ledNumber);
6     }
7
8     public void ledsOff(){
9         Storage.ledsOff();
10    }
11
12    public boolean switch1Pressed(){
13        // todo for now returns false
14        if (Storage.getSwitch1() == 1) return true;
15        return false;
16    }
17
18    public boolean switch2Pressed(){
19        // todo for now returns false
20        return false;
21    }
22
23    public boolean bothSwitchesPressed(){
24        // todo for now returns false
25        return false;
26    }
27
28    public void putPartInCell(){
29        // todo
30    }
31
32    public void takePartFromCell(){
33        //todo
34    }
35 }
36
```

The class mechanism deals with:

- the LEDs
- the switches
- the movements to insert and take parts from cell

Remember, some of these methods might be static, others not

Static methods do not use any instance variables of any object of the class they are defined in. Static methods take all the data from parameters and compute something from those parameters, with no reference to variables.

WHY THREADS?

REVIEW

NOVA

- ☐ Start thinking of which THREADS are needed to be executed synchronously or in parallel.
- ☐ Tip: start by implementing **thread_calibrate**, **thread_gotoX** and **thread_gotoZ...**
- ☐ Draw a first diagram illustrating the threads and the interactions between them.

TO STUDY....

Check....

<https://docs.oracle.com/javase/8/docs/api/index.html>

The screenshot shows the Java API documentation for the `Thread` class. The left sidebar lists various packages, with `java.lang` selected. The main content area shows the `Thread` class, which is highlighted with a red box. The class is described as a thread of execution in a program. It implements the `Runnable` interface. The documentation includes a description of threads, their priority, and how to create a new thread. A code snippet shows a subclass of `Thread` named `PrimeThread`.

```
class PrimeThread extends Thread {
    long minPrime;
    PrimeThread(long minPrime) {
        this.minPrime = minPrime;
    }
}
```

REVIEW

NVA

The screenshot shows the Java API documentation for the `java.util.concurrent` package. The left sidebar lists various packages, with `java.util.concurrent` selected. The main content area shows the package summary, which is highlighted with a red box. The package is described as utility classes commonly useful in concurrent programming. The documentation includes a table of interfaces and classes, with a description for each.

Interface	Description
<code>BlockingDeque<E></code>	A <code>Deque</code> that additionally supports blocking operations that wait for the deque to become non-empty when retrieving an element, and wait for space to become available in the deque when storing an element.
<code>BlockingQueue<E></code>	A <code>Queue</code> that additionally supports operations that wait for the queue to become non-empty when retrieving an element, and wait for space to become available in the queue when storing an element.
<code>Callable<V></code>	A task that returns a result and may throw an exception.
<code>CompletableFuture.AsyncronousCompletionTask</code>	A marker interface identifying asynchronous tasks produced by async methods.
<code>CompletionService<V></code>	A service that decouples the production of new asynchronous tasks from the consumption of the results of completed tasks.
<code>CompletionStage<T></code>	A stage of a possibly asynchronous computation, that performs an action or computes a value when another <code>CompletionStage</code> completes.
<code>ConcurrentMap<K,V></code>	A <code>Map</code> providing thread safety and atomicity guarantees.
<code>ConcurrentNavigableMap<K,V></code>	A <code>ConcurrentMap</code> supporting <code>NavigableMap</code> operations, and recursively so for its navigable sub-maps.
<code>Delayed</code>	A mix-in style interface for marking objects that should be acted upon after a given delay.
<code>Executor</code>	An object that executes submitted <code>Runnable</code> tasks.
<code>ExecutorService</code>	An <code>Executor</code> that provides methods to manage termination and methods that can produce a <code>Future</code> for tracking progress of one or more asynchronous tasks.
<code>ForkJoinPool.ForkJoinWorkerThreadFactory</code>	Factory for creating new <code>ForkJoinWorkerThreads</code> .
<code>ForkJoinPool.ManagedBlocker</code>	Interface for extending managed parallelism for tasks running in <code>ForkJoinPools</code> .

<https://docs.oracle.com/javase/8/docs/api/index.html?java/util/concurrent/package-summary.html>

THREADS – SOME ASPECTS TO CONSIDER

Two ways to start a thread (1)

```
@FunctionalInterface  
public interface Runnable
```

The Runnable interface should be implemented by any class whose instances are intended to be executed by a thread. The class must define a method of no arguments called run.

<https://docs.oracle.com/javase/8/docs/api/index.html>

In order to create **threads**, we need to provide a runnable object, as shown in the example.

Any Runnable class must implement the method **run()**.

Notice that HelloRunnable has got this method.

```
public class HelloRunnable implements Runnable {  
    @Override  
    public void run() {  
        System.out.println("Hello from thread!");  
    }  
    public static void main(String[] args) {  
        (new Thread(new HelloRunnable())).start();  
    }  
}
```

https://en.wikipedia.org/wiki/Java_concurrency

THREADS – SOME ASPECTS TO CONSIDER

Two ways to start a thread (2)

```
public class Thread  
    extends Object  
    implements Runnable
```

A *thread* is a thread of execution in a program. The Java Virtual Machine allows an application to have multiple threads of execution running concurrently.

Every thread has a priority. Threads with higher priority are executed in preference to threads with lower priority. Each t

<https://docs.oracle.com/javase/8/docs/api/index.html>

In order to create threads, we need to implement a subclass of **Thread**.

```
public class HelloThread extends Thread {  
    @Override  
    public void run() {  
        System.out.println("Hello from thread!");  
    }  
    public static void main(String[] args) {  
        (new HelloThread()).start();  
    }  
}
```

https://en.wikipedia.org/wiki/Java_concurrency

THREADS – ASPECTS TO CONSIDER

Waiting for threads termination: `Thread.join`

- When **Thread.join** is called, it suspends the execution of the calling thread until the target thread is alive.
- Once the target thread is done with its job and terminates, the caller thread will automatically wake up.
In the diagram, the caller thread starts two threads t1 and t2, each thread is assigned one specific task.
- The caller thread then calls on **t1.join** so that it is blocked from further execution till t1 finishes its job.
Once t1 is done with its execution and terminates, it wakes up the caller thread.
Next, caller thread calls **t2.join** to wait on t2 till it is done with its task.
Once t2 finished, caller thread wakes up and continues in its execution.

`join()`

Waits for this thread to die.

<https://docs.oracle.com/javase/8/docs/api/index.html>

<https://examples.javacodegeeks.com/core-java/threads/java-thread-join-example/>

SHORT-LIVED THREADS

Threads which start execution, perform their job in a concurrent way, and complete....

Generally, they perform a single job then finish.

Additionally, we might **synchronize** them (as illustrated in the picture), but not strictly necessary....

SHORT-LIVED THREADS - EXAMPLES

Single-Thread (implicit MainThread)

```
5
6 public class SortExample {
7     public static int[] generateHugeArray(int size){
8         Random rd = new Random(); //creating Random object
9         int[] arr = new int[size];
10        for (int i = 0; i < arr.length; i++){
11            arr[i] = rd.nextInt(); // storing random integres in an array
12        }
13        return arr;
14    }
15 }
```

Run | Debug

```
16 public static void main(String[] args){
17     // Our arr contains 8 elements
18     // int[] arr = {13, 8, 5, 78, 21, 7, 101, 156}
19
20     int arr1[] = generateHugeArray(size:2000000);
21     int arr2[] = generateHugeArray(size:2000000);
22
23     long ti = System.currentTimeMillis();
24     Arrays.sort(arr1);
25     Arrays.sort(arr2);
26     long tf = System.currentTimeMillis();
27
28     System.out.printf(format:"Time : %d milliseconds", tf-ti);
29 }
30 }
31

LONG-LIVED THREADS

Threads that after being created, stay handling the problems for a long time.

They are structured in a loop-like way, holding-on for a new Job/problem to work on,

...exhibiting multi-tasking cooperative, and reactive, behavior patterns

In many situations, long-lived threads are desirable, to reduce overhead for task creation, memory garbage collection..., less dynamic allocation

LONG-LIVED THREADS - EXAMPLE

```
6 public class ServerThread extends Thread{
7     private boolean interrupted;
8
9     public boolean isInterrupted(){
10         return interrupted;
11     }
12
13     public void setInterrupted(boolean interrupted){
14         this.interrupted = interrupted;
15     }
16
17     public void run(){
18         this.setInterrupted(interrupted:false);
19         while(!interrupted){
20             //do something
21             System.out.println(x:"doing some task here until interrupted");
22             try {
23                 Thread.sleep(millis:1000);
24             } catch (InterruptedException e) {
25                 e.printStackTrace();
26                 Logger.getLogger(ServerThread.class.getName()).log(Level.SEVERE, msg:null, e);
27             }
28         }
29     }
30
31     public static void main(String[] args) throws InterruptedException{
32         ServerThread worker = new ServerThread();
33         worker.start();
34         Thread.sleep(millis:3000);
35         worker.setInterrupted(interrupted:true);
36         System.out.println(x:"Thread was interrupted");
37     }
38 }
39
```

Usually in a **while(true) {...} loop** until interrupted

The **interrupted variable** can be set internally (inside the loop), or externally (in other part of the Java application)

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL PORTS

Run: ServerThread

```
PS C:\STR\Labwork2\labwork2> & 'C:\Users\faf\AppData\Local\Programs\Eclipse Adoptium\jdk-17.0.4.101-hotspot\bin\java.exe' '-XX:+ShowCodeDetailsInExceptionMessages' '-cp' 'C:\STR\Labwork2\labwork2\target\classes' 'str.ServerThread'
doing some task here until interrupted
doing some task here until interrupted
doing some task here until interrupted
Thread was interrupted
```

SYNCHRONIZATION WITH A SEMAPHORE

```
import java.util.concurrent.Semaphore;
import java.util.logging.Level;
import java.util.logging.Logger;

public class ServerThread extends Thread{

    private boolean interrupted = false;
    private Semaphore semaphoreSync = null;

    public ServerThread(){
        this.semaphoreSync = new Semaphore(permits:0);
    }

    public void signalWork() {
        semaphoreSync.release();
    }

    public boolean isInterrupted(){
        return this.interrupted;
    }

    // interrompe e acorda a thread caso esteja em acquire()
    public void setInterrupted(boolean interrupted){
        this.interrupted = interrupted;
        this.semaphoreSync.release();
    }

    public void run() {
        try{
            while(!this.isInterrupted()){
                this.semaphoreSync.acquire();
                if (this.isInterrupted()) break; // sai se já tiver sido interrompida
                System.out.println(x:"doing some task here until interrupted");
            }
        }catch(InterruptedException e){
            Logger.getLogger(ServerThread.class.getName()).log(Level.SEVERE, msg:null, e);
        }
    }

    Run | Debug
    public static void main(String[] args) throws InterruptedException{
        ServerThread worker = new ServerThread();
        worker.start();

        // sinaliza algum trabalho
        worker.signalWork();
        worker.signalWork();
        worker.signalWork();

        // dá tempo à thread para consumir e imprimir
        Thread.sleep(millis:200);

        worker.setInterrupted(interrupted:true);
        worker.join();
        System.out.println(x:"Thread was interrupted");
    }
}
```

Using the previous example, we can use a Java semaphore to synchronize work.

After three **releases/signalWork**, the Thread blocks by the semaphore *acquire()*, until more releases.

In this example, a manually created *boolean* variable called **interrupted** is being used to control when the thread should stop.

However, Java already provides its own **built-in mechanism** for interrupting threads, using **Thread.interrupt()**, **isInterrupted()**, and the **InterruptedException**.

This approach is problematic because:

- The programmer's custom *boolean* is **not safely shared** between threads: one thread might change its value, but the other thread may never "see" that change.
- The thread can become **blocked** in operations like *acquire()* and never stop, even if the *boolean* value changes.
- The code **does not follow Java's best practices**, and it can easily lead to confusion or errors when you start using more advanced Java libraries and concurrency tools.

rewrite the code using Java's native interruption mechanism.

BLOCKING QUEUE EXAMPLE

```
public class ServerThread2 extends Thread{
    private boolean interrupted;
    private ArrayBlockingQueue<Integer> queue = null;

    public ServerThread2(){
        this.queue = new ArrayBlockingQueue<Integer>(capacity:10);
    }

    public boolean isInterrupted(){
        return interrupted;
    }

    public void setInterrupted(boolean interrupted){
        this.interrupted = interrupted;
    }

    public ArrayBlockingQueue <Integer> getQueue(){
        return this.queue;
    }

    public void run(){
        this.setInterrupted(interrupted:false);
        while(!interrupted){
            try {
                int x = this.queue.take();
                System.out.printf(format:"\n got %d...", x);
            } catch (InterruptedException e) {
                Logger.getLogger(ServerThread2.class.getName()).log(Level.SEVERE, msg:null, e);
            }
        }
    }
}

Run | Debug
public static void main(String[] args) throws InterruptedException{
    ServerThread2 worker = new ServerThread2();
    worker.start();
    ArrayBlockingQueue<Integer> q1 = worker.getQueue();
    q1.add(e:100);
    q1.add(e:200);
    q1.add(e:300);
    worker.setInterrupted(interrupted:true); // it does not work. why?
    System.out.println(x:"Thread was interrupted");
}
```

The example illustrates a utilization of a blocking queue in a thread.

Inside the **run()** method, the thread keeps blocked in the **take()** method until a new message (an integer value) arrives.

The program does not work... why?? Look at the previous example....

BLOCKING QUEUE – OTHER EXAMPLES

From the JavaDocs:

- A [ConcurrentLinkedQueue](#) is an appropriate choice when many threads will share access to a common collection. This queue does not permit null elements.
- [ArrayBlockingQueue](#) is a classic "bounded buffer", in which a fixed-sized array holds elements inserted by producers and extracted by consumers. This class supports an optional fairness policy for ordering waiting producer and consumer threads
- [LinkedBlockingQueue](#) typically have higher throughput than array-based queues but less predictable performance in most concurrent applications.

Interface	Description
BlockingDeque<E>	A Deque that additionally supports blocking operations that wait for the deque to become non-empty when retrieving an element, and wait for space to become available in the deque when storing an element.
BlockingQueue<E>	A Queue that additionally supports operations that wait for the queue to become non-empty when retrieving an element, and wait for space to become available in the queue when storing an element.
Callable<V>	A task that returns a result and may throw an exception.
CompletableFuture , AsynchronousCompletionTask	A marker interface identifying asynchronous tasks produced by async methods.
CompletionService<V>	A service that decouples the production of new asynchronous tasks from the consumption of the results of completed tasks.
CompletionStage<T>	A stage of a possibly asynchronous computation, that performs an action or computes a value when another CompletionStage completes.
ConcurrentMap<K,V>	A Map providing thread safety and atomicity guarantees.
ConcurrentNavigableMap<K,V>	A ConcurrentMap supporting NavigableMap operations, and recursively so for its navigable sub-maps.
Delayed	A mix-in style interface for marking objects that should be acted upon after a given delay.
Executor	An object that executes submitted Runnable tasks.
ExecutorService	An Executor that provides methods to manage termination and methods that can produce a Future for tracking progress of one or more asynchronous tasks.
ForkJoinPool , ForkJoinWorkerThreadFactory	Factory for creating new ForkJoinWorkerThreads .
ForkJoinPool , ManagedBlocker	Interface for extending managed parallelism for tasks running in ForkJoinPools .

SUGGESTIONS FOR LAB WORK 2

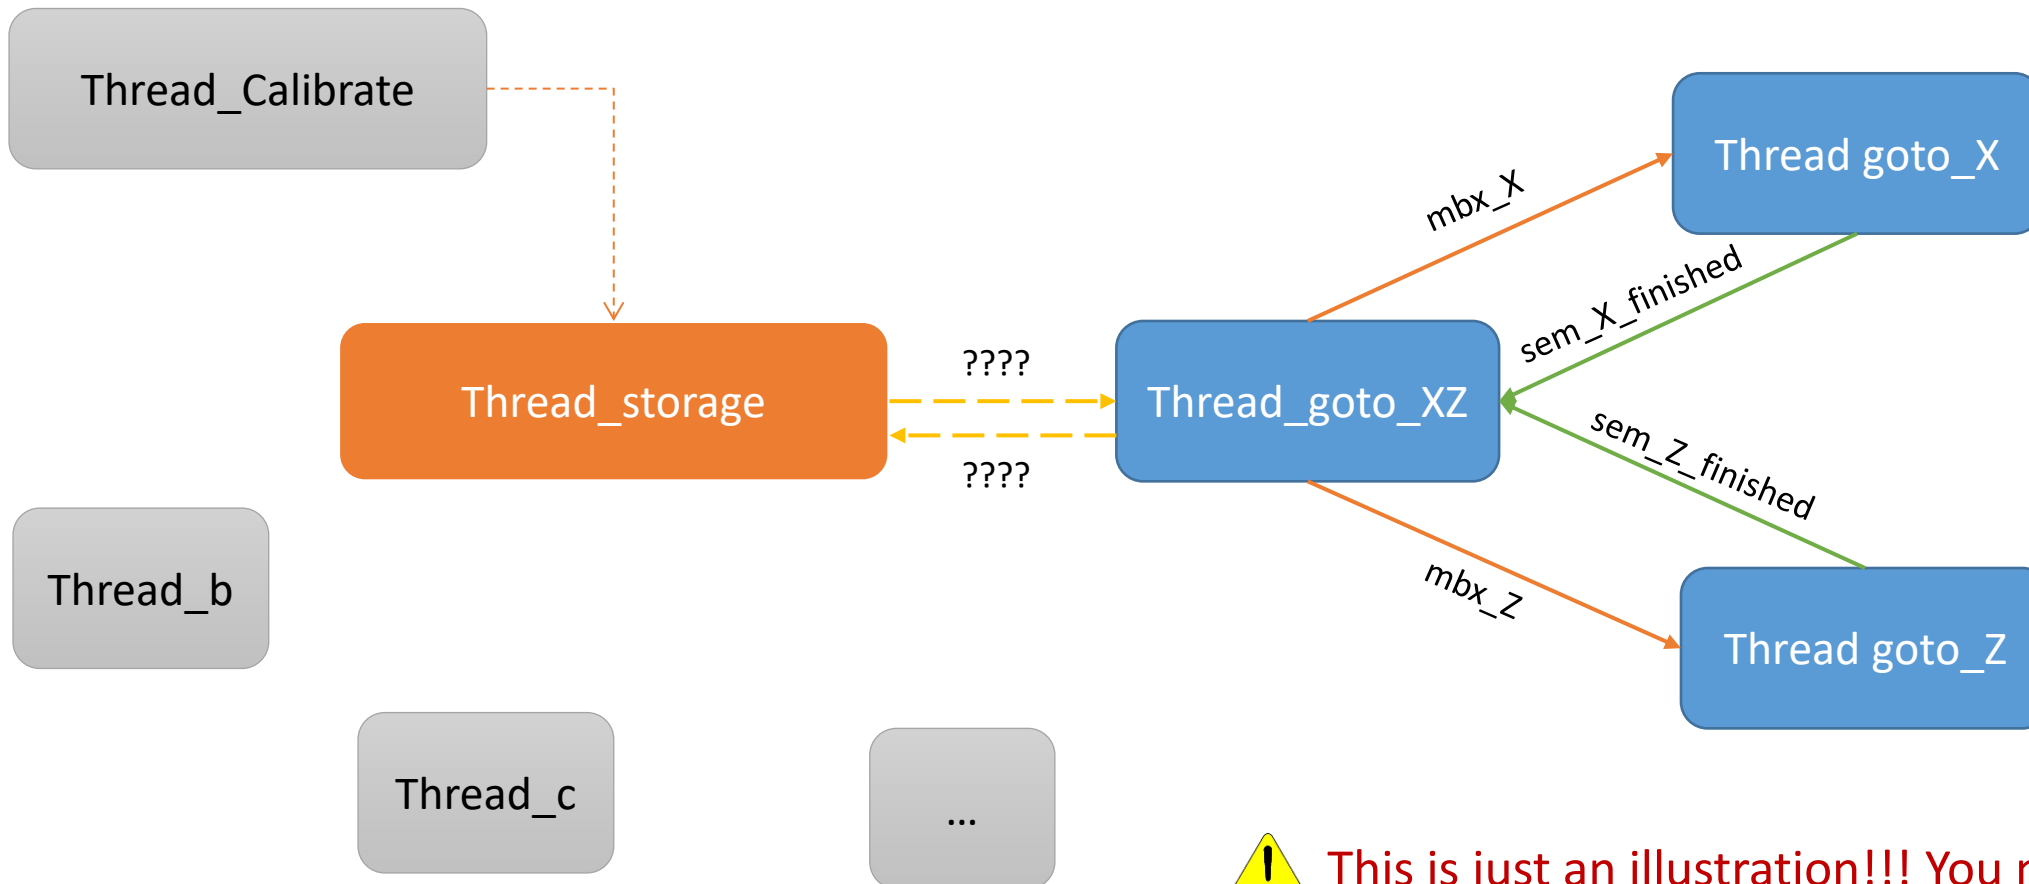

Req.	Description
	Low-level requirements (DLL development):
RL1	User Keyboard interaction providing execution of actions and showing warehouse states.
RL2	Develop the DLL and expose low-level I/O functions through JNI .
	High-level requirements (Java Development)
RH1	<i>Calibration</i> . Develop robust (semi-automatic) storage calibration. During a movement, the actuator must stop when it reaches a position sensor. It should always initiate with the cage in position (X=1, Z=1, Y=2).
RH2	<i>Manual Storage</i> . Store a pallet in the storage. Ask for pallet metadata (product_type, humidity, producer_ID, destination, shipping date) and target cell (X,Z). Validate if cell is empty.
RH3	<i>Assisted storage</i> . When (X,Z) is not provided, invoke the “AI-Assisted Placement Module” recommender (balance occupancy, group by type, minimize travel distance). Based on log decisions.
RH4	<i>Deliver pallet by cell (X,Z)</i> . Retrieve the pallet from cell (X,Z) specified through keyboard and unload based on the active mode: Mode 1: unload at (X=3, Z=1) with Y=1. Mode 2: unload at (X, Z=1) with Y=1 and LED2 flashing during the process.
RH5	<i>Deliver by product or producer</i> . List and deliver matching pallets.
RH6	<i>Shipping and humidity alerts</i> . Flash LED1 when a pallet’s shipping date arrives or humidity exceeds a threshold (threshold may be defined by the student and must be documented).
RH7	<i>Mass removal (Switch 1)</i> . Remove all pallets with active alerts; LED1 flashes until process completes.
RH8	<i>Emergency STOP (Switch 1 + Switch 2)</i> . Emergency! Stop motion and freeze operations.
RH9	<i>Resume (Switch 1)</i> . During an emergency STOP, if switch 1 is pressed, then RESUME operation.
RH10	<i>Reset (Switch 2)</i> . During an emergency STOP, if switch 2 is pressed, then RESET the system (perform semi-automatic storage calibration).
RH11	<i>Emergency indicators</i> . Both LEDs flash rapidly (0.5 s) during emergency until resume/reset.
RH12	<i>Product list</i> . Display list of stored pallets (product types, producer IDs, humidity and shipping dates).
RH13	<i>Pallet lookup</i> . Display (X,Z), humidity, destination, and shipping info for selected product type/producer.

- Brainstorm your lab work to perceive which threads should be short lived or to persist.
- Could an information thread be a long-running one?
- Explore the `java.util.concurrent` and decide which concurrent mechanisms can be used to faithfully satisfy the requirements in the lab work.
- However, Keep it simple (but not simplistic).

□ Let's start by designing a diagram of threads and inter-threads interactions:

This is just an illustration!!! You must adapt it according with your approach...

Aspects to consider....

```
1 package str;
2
3 public class CalibrationThread extends Thread{
4     private final Axis axis;
5
6     public CalibrationThread(Axis axis){
7         this.axis = axis;
8     }
9
10    public void initializeCalibration(){
11        if (axis.getPos() == -1) {
12            axis.moveForward();
13            while (axis.getPos() == -1 || axis.getPos() > 3) { }
14            axis.stop();
15            if (axis.getPos() > 1) {
16                axis.gotoPos(pos:1); //with exception of Y axis!!!
17            }
18        }
19    }
20
21    @Override
22    public void run() {
23        this.initializeCalibration();
24    }
25 }
26
```

The class **CalibrationThread** might be defined as shown on the right.

Its constructor accepts an object that implements the interface **Axis**.

This means that **CalibrationThread** can accept and operate with any of the objects instantiated from class AxisX, AxisZ or AxisY (attention with AxisY, Y = 1 is not calibrated...).

In this example, regardless of which axis provided, after calling the start() method, the **CalibrationThread** should sequentially call getPos, moveForward, etc.. of the provided axis.

KEEP UP THE
GOOD
WORK!
